

Background-only signal extraction

Ensemble mean amplitude relative to the fixed reference uncertainty σ_{ref}

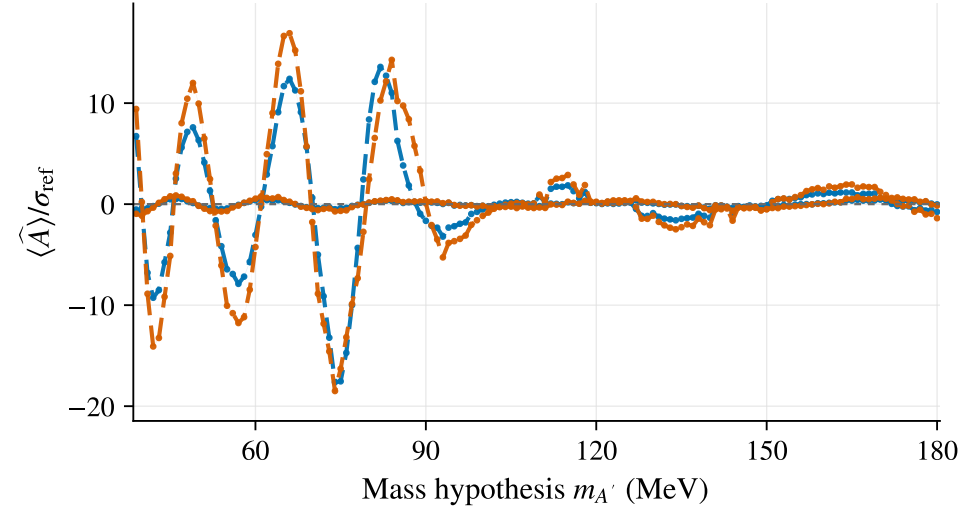

— Gaussian profile — Fixed GP mean — GP mean truth — Archived stress truth

Complete mass grid: 456 of 456 mass hypotheses; 500 independent spectra per cell

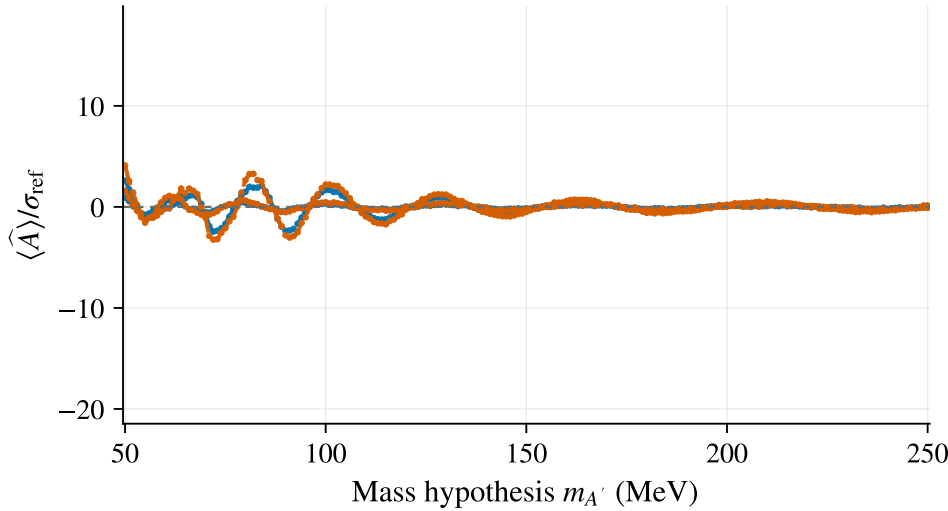

2015, full sample

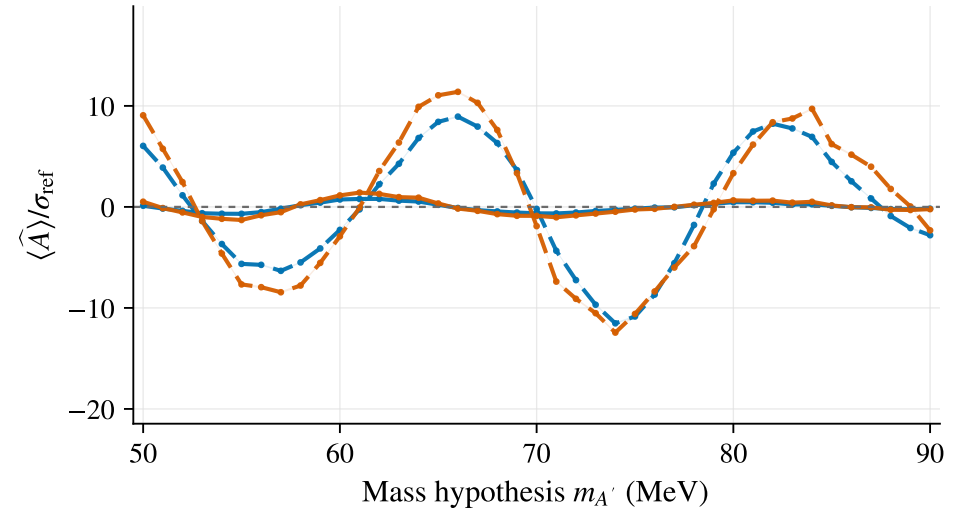

2016, full sample

2021, 10% sample

All three, shared coupling

Shading: approximate pointwise 95% Monte Carlo intervals for the ensemble mean; no simultaneous band.

σ_{ref} is the frozen Gaussian-profile Fisher uncertainty at each mass, common to both methods.

This is a mean amplitude in fixed reference units, not the historical mean of per-toy pulls. No counts are pooled.
