

v4.8 rigid threshold stress mean: conditional zero-signal spurious-signal diagnostic

Each lane uses 20 analyzed backgrounds; masses share backgrounds and exposure lanes are nested within source family. All finite pulls set the axes; no clipping is applied. The 90% t/chi-square intervals are finite-ensemble diagnostics, not 90% CLs. This figure is not coverage, observed-data bias, an expected band, or a physical-background claim.
